

A new 6-year-old pediatric patient walks into your operatory with **her** mother. Your initial physical assessment notes a prominent forehead and flattened nose. The patient initially seems to have no eyebrows but you later realize that the hair is just very fine and sparse. When you shake her hand and she smiles, you also notice that she is missing teeth and the ones she has are cone shaped. What is her most likely systemic condition?

- pierre robin syndrome
- ectodermal dysplasia
- cleidocranial dysplasia
- peutz-jeghers syndrome
- osteopetrosis
